“Any big experiment should boost development of new experimental techniques which will pave the way for new, more sensitive experiments

A.E.Chudakov

First generation of large scale neutrino experiments (underground water Cherenkov arrays)

IMB

8" R1408

Kamiokande - Super-Kamiokande

20" R1449

20" R3600

- Detection of neutrino signal from SN1987A
- Discovery of neutrino oscillation

Deep underwater neutrino experiments

iev,
Lyon 6 July 20

XP2600 PHILIPS/PHOTONIS

QUASAR-370 KATOD/INR

Record timing and excellent SER

- Proof of principle of high energy neutrino detection
- Discovery of fresh water luminescence
- Discovery of fresh water bioluminescent microflashes

Next generation neutrino experiments

Water Cherenkov experiments

UNO, DUE, TRE

UNO: 80 000 20" PMTs

DUE: ~200 000 20" PMTs

TRE: ~200 000 20" PMTs

Liquid scintillator experiment LENA

DETECTOR LAYOUT

Cavern

height: 115 m, diameter: 50 m
shielding from cosmic rays: ~4,000 m.w

Muon Veto

plastic scintillator panels (on top)
Water Cherenkov Detector
1,500 phototubes
100 kt of water
reduction of fast
neutron background

Steel Cylinder

height: 100 m, diameter: 30 m
70 kt of organic liquid
13,500 phototubes

Buffer

thickness: 2 m
non-scintillating organic liquid
shielding external radioactivity

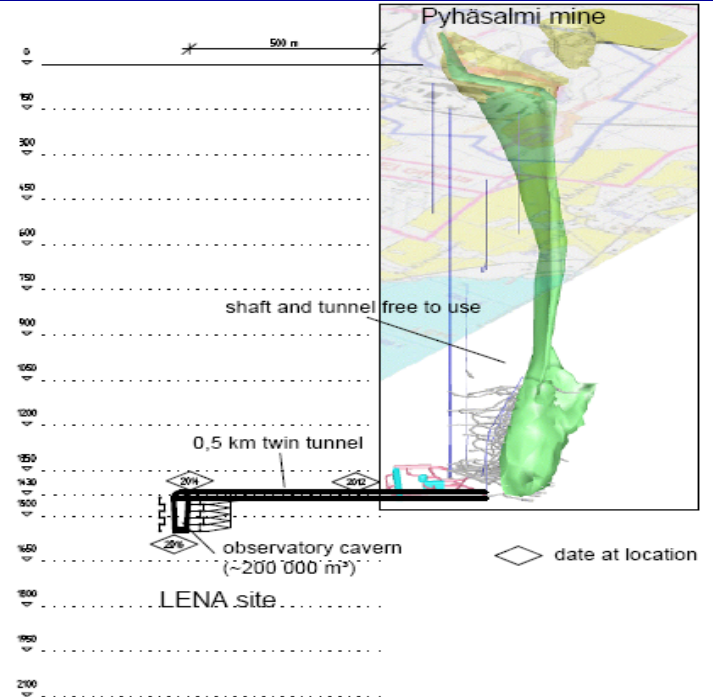

Nylon Vessel

parting buffer liquid
from liquid scintillator

Target Volume

height: 100 m, diameter: 26 m
50 kt of liquid scintillator

vertical design is favourable in terms of rock pressure and buoyancy forces

Schedule (excavation works):

- start 2012 earliest
- duration 4 years
- finish in 2016

Challenge to the development of large sensitive area photodetectors

Conventional PMTs or Hybrid Tubes?

Hybrid tubes have record timing and excellent SER

BUT

There is one substantial drawback --- slow time response due to scintillator light emission kinetics

Solution ---- fast high efficiency scintillators

G - the first stage amplification factor of hybrid tubes

$$G = Y \times k \times \eta(\text{eff})$$

Y - scintillator light yield

k - collection efficiency of photons on the small PMT's photocathode

$\eta(\text{eff})$ - effective quantum efficiency of the small PMT

Small PMT with higher effective QE will provide better parameters

Requirements for scintillators:

- high light yield
- fast emission kinetics
- vacuum compatibility
- compatibility with photocathode manufacturing procedure:
high temperature, aggressive chemical environment etc.

Scintillators have to be:

Inorganic

Nonhygroscopic

Time resolution of hybrid phototubes and scintillator parameters

$$W(t) \sim \exp(-(G/\tau)t)$$

G - the first stage amplification factor

$$G = n_{p.e.} / N_{p.e.}$$

$n_{p.e.}$ - # of p.e. detected by small PMT; $N_{p.e.}$ - # of p.e. on the phototube cathode

$$G \sim Y(E_e)$$

Y - scintillator light yield

τ - scintillator decay time

Scintillator should have Y/τ as high as possible

ZnO:Ga

Luckey D., 1968 NIM

Light yield = NaI(Tl); Decay time - 0.4 ns!

W.Moses. NIMA (LBNL-50252)

Light yield - 15000 γ /MeV; Decay time - 0.4 ns.

Hypothetical hybrid tube with ZnO:Ga and high QE fast small PMT would be a fantastic photodetector with <1ns jitter (FWHM) and <1ns anode pulse width!

“ZnO:Ga – ideal scintillator for hybrid tubes” *B.Lubsandorzhiev and B.Combettes TNS 2008*

ZnO:Ga crystals from Cermet Inc. Atlanta, GA, USA

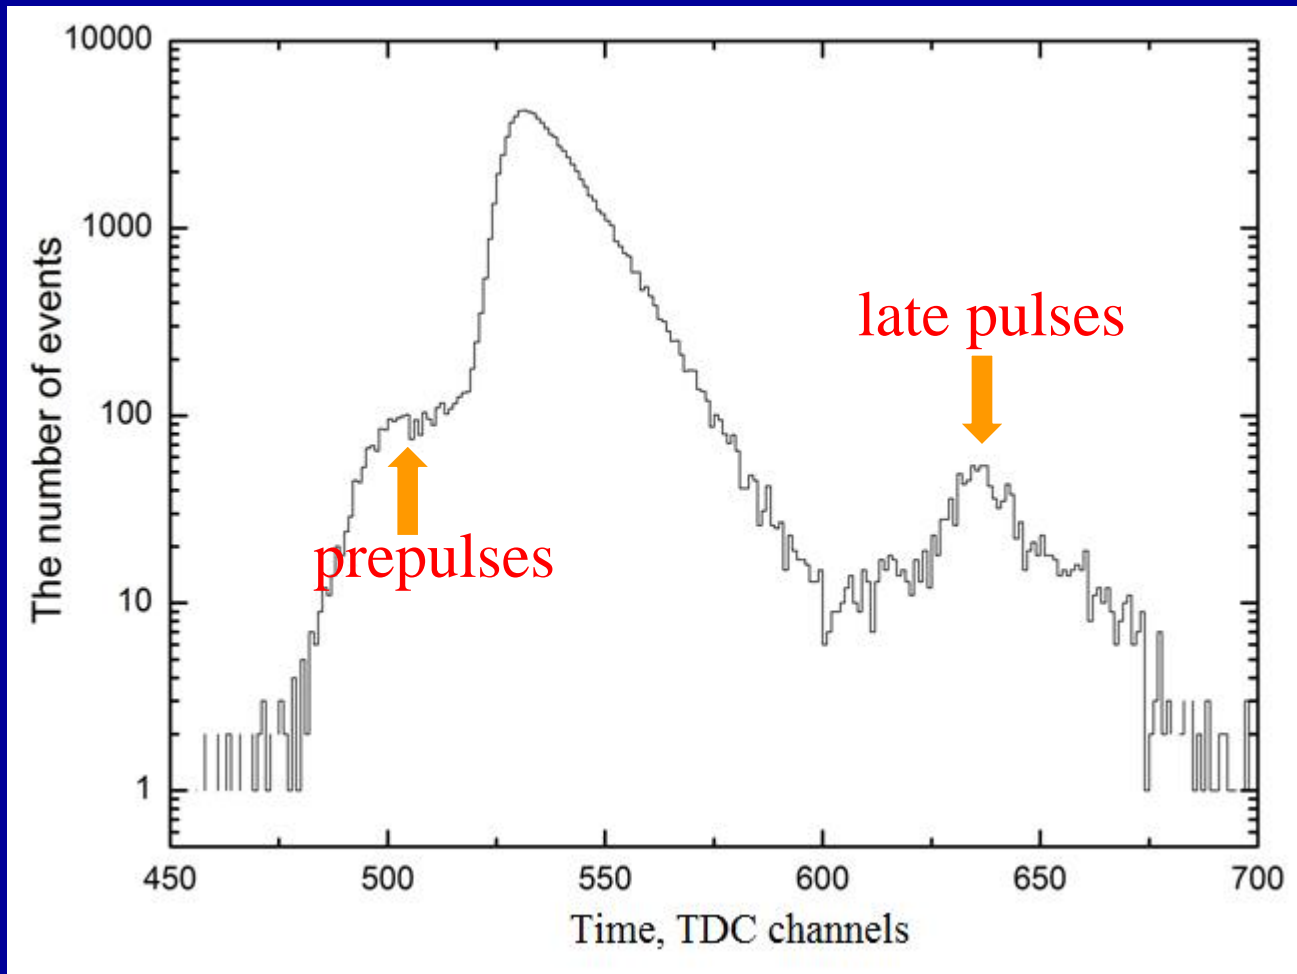

~300 μ thickness

~1cm² area

$\lambda_{\text{max}} \sim 390 \text{ nm}$

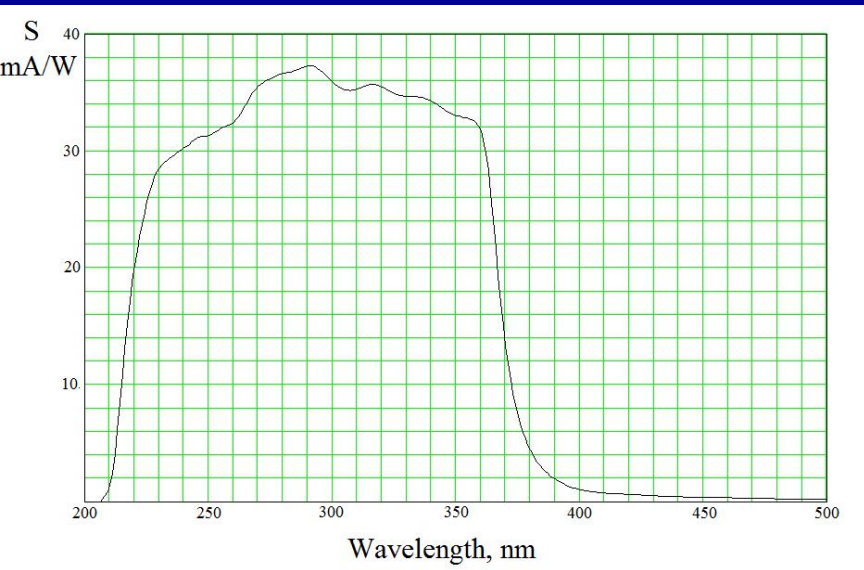

$\tau \sim 650$ ps, light yield ~ 1200 γ /MeV

Pilot sample of HPD with ZnO:Ga crystal based on image intensifier

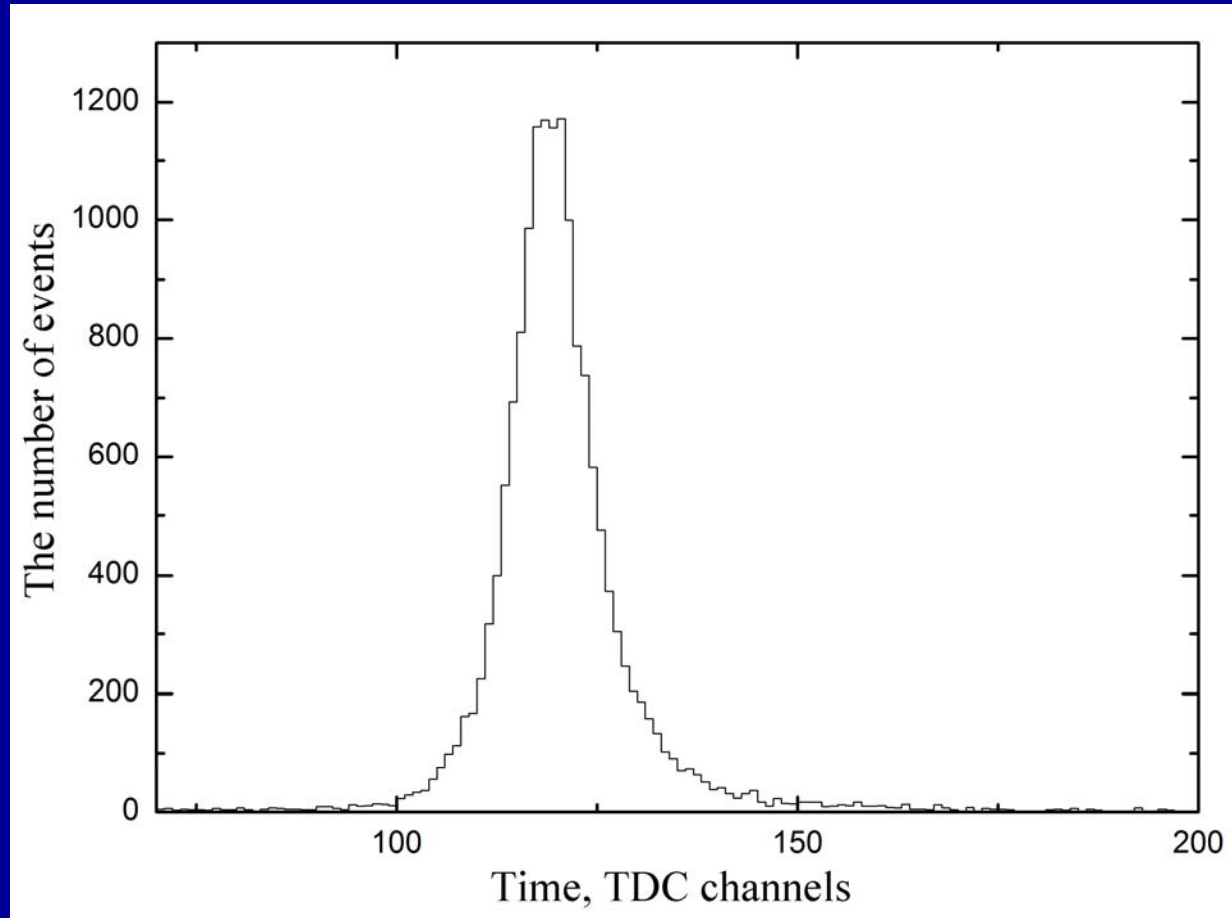

Pilot sample's GaN photocathode sensitivity

QE ~ 17%

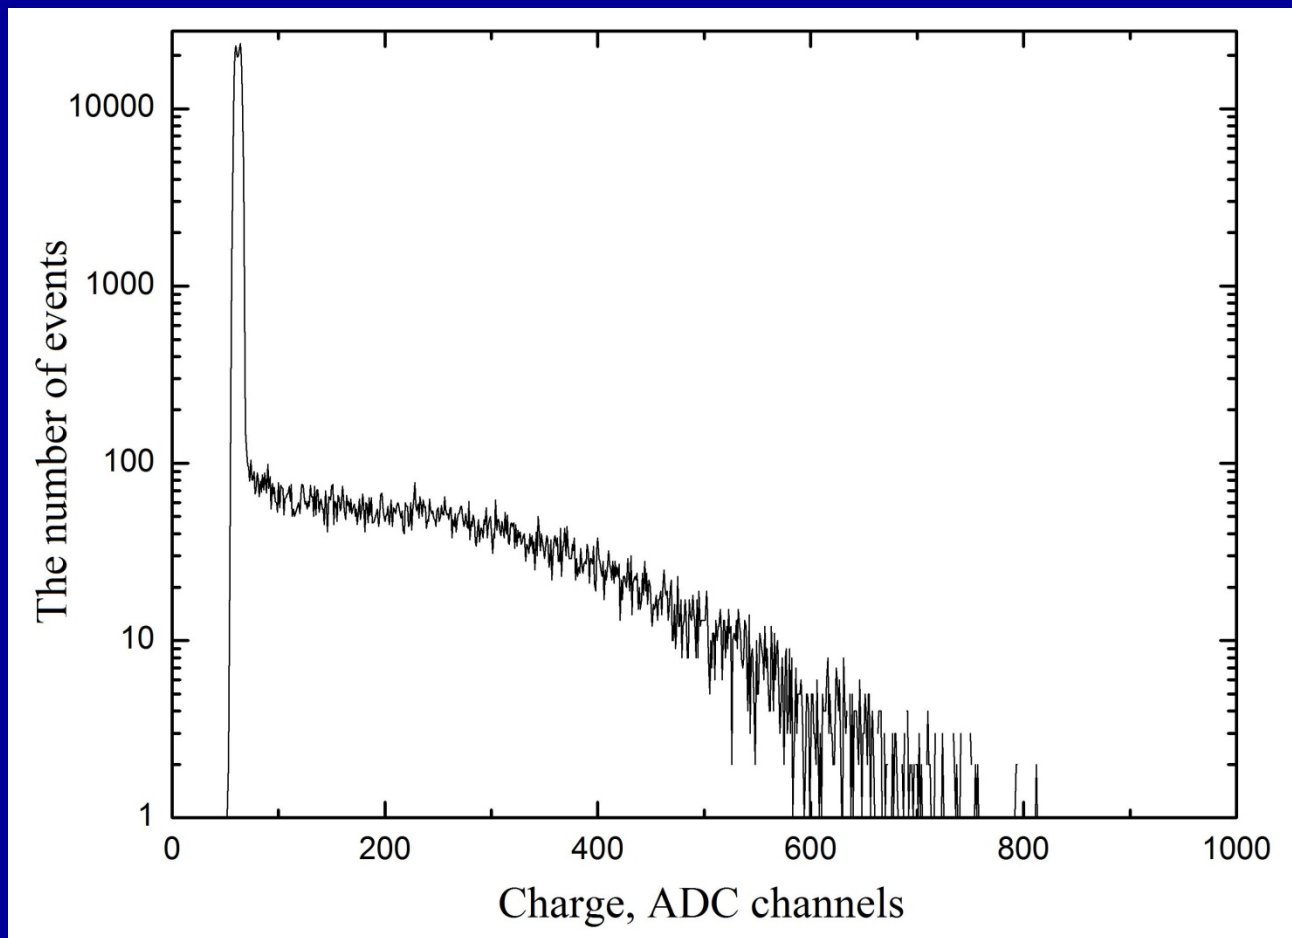

Jitter (TTS)

$$\Delta t_{\text{hpd}} \sim 750 \text{ ps (FWHM)}; \quad \Delta t_{\text{LED}} \sim 700 \text{ ps}$$

Single electron response

Practically no single pe peak

There is at least one application for which hybrid tubes equipped with the ZnO:Ga crystals with the light yield even at present level are very interesting

Wide angle EAS Cherenkov Arrays

(TUNKA, SCORE, LHAASO, Auger-Next etc)

TUNKA EAS Cherenkov experiment

$E_0 \sim Q_{total}$
 (Q_{total} - Cherenkov light flux)

X_{max} measurement:
 (model independent)

2. WDF $\Delta t_{fwhm} \sim \Delta X$ [g/cm²]
 $\Delta X = X_0 / \cos\theta - X_{max}$

1. LDF steepness
 $H_{max} = a - b \cdot P$

Primary nucleus $E_0, A?$
 $\langle X_{max} \rangle \sim \langle \ln A \rangle$

Primary cosmic rays studies
 in the energy range of 10^{15} - 10^{18} eV

Width of EAS Cherenkov signals is
 sensitive to the mass composition
 of primary cosmic rays

No need to operate in 1 pe mode
 (threshold ≥ 100 pe)

CONCLUSION

ZnO:Ga is a very promising scintillator for hybrid phototubes with luminescent screens

It is necessary to increase the light yield of the crystals

The search for new fast scintillator materials of high efficiency should be continued
