In the framework of the ALICE upgrade program we are investigating the possibility to build a new RICH detector allowing to extend the particle identification for hadrons up to 30 GeV/c .**It is called VHMPID**.

The **VHMPID** should be able to identify, on a track-by-track basis, protons enabling to study the leading particles composition in jets (correlated with the  $\pi^0$  and /or  $\gamma$  energies deposited in the electromagnetic calorimeter).

The suggested detector will consist of a gaseous radiator (for example,  $\text{CF}_4$  or  $\text{C}_4\text{F}_{10}$ ) and a planar gaseous photodetector

The key element of the VHMPID is a planar photodetector

There are **two** options for planar photodetectors which are currently under evaluation:

← **MWPC**  
(similar to one used in ALICE RICH)

or

**TGEMs/RETGEMs**

For TGEM see : *L. Periale et al., NIM A478,2002,377,*  
*S. Chalem et al., NIM A558, 2006, 475*

The aim of this work is to build a  
CsI-TGEM based RICH  
prototype, perform it beam test  
and compare to the MWPC  
approach

# TGEM

TGEM is a hole-type gaseous multiplier based on standard printed circuit boards featuring a combination of mechanical drilling (by a CNC drilling machine) and etching techniques.

**Thickness: 0.45 mm**  
**Hole d: 0.4 mm**  
**Rims: 10  $\mu$ m**  
**Pitch: 0.8 mm**  
**Active area: 77%**

100mm

# The operation principle of the CsI coated triple TGEM (CsI -TGEM)

TGEMs have several attractive features compared to ordinary GEMs:

- 1) ~10 times higher gains
- 2) robustness- capability to withstand sparks without being destroyed
- 3) it is a self-supporting mechanical structure making their use convenient in large detectors

## CsI-TGEMs, have some advantages, over MWPC for example:

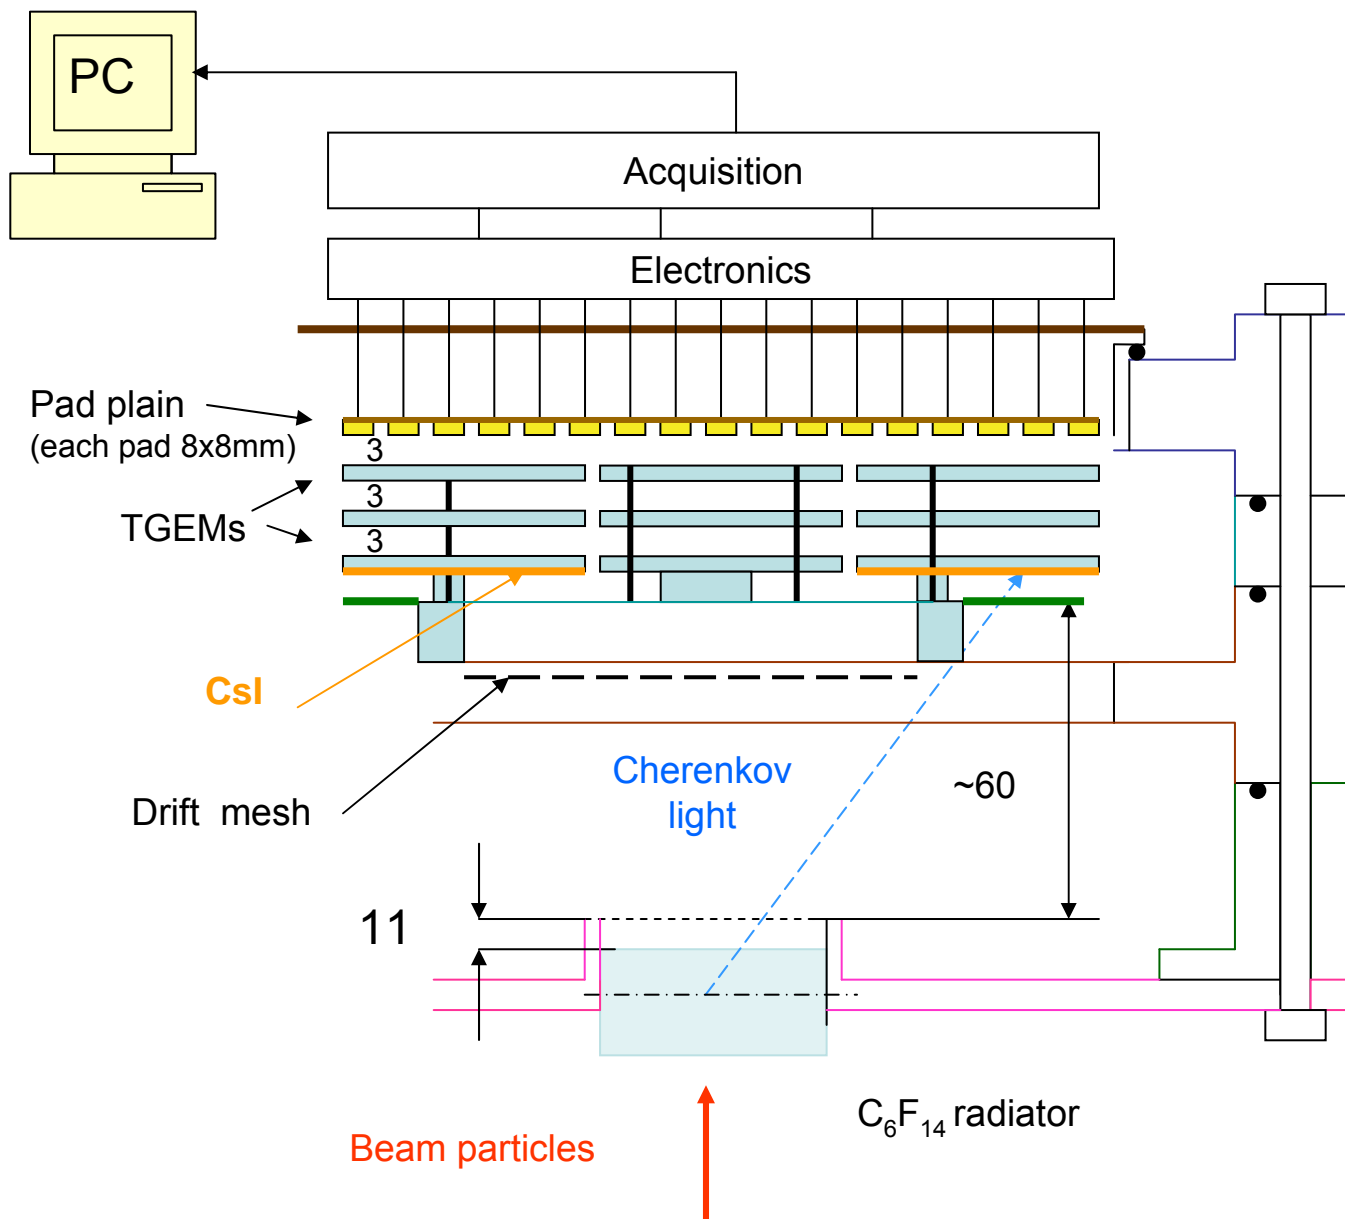

- CsI-TGEM can operate in badly quenched gases as well as in gases in which are strong UV emitters. This allows to achieve high gains without feedback problems. This also opens a possibility to use them in unflammable gases or if necessary using windowless detectors (as in PHENIX)

- In some experiments, if necessary CsI-TGEMs, can operate in “hadron blind mode” with zero and even reversed electric field in the drift region which allows strongly suppress the ionization signal from charged particles (PHENIX)

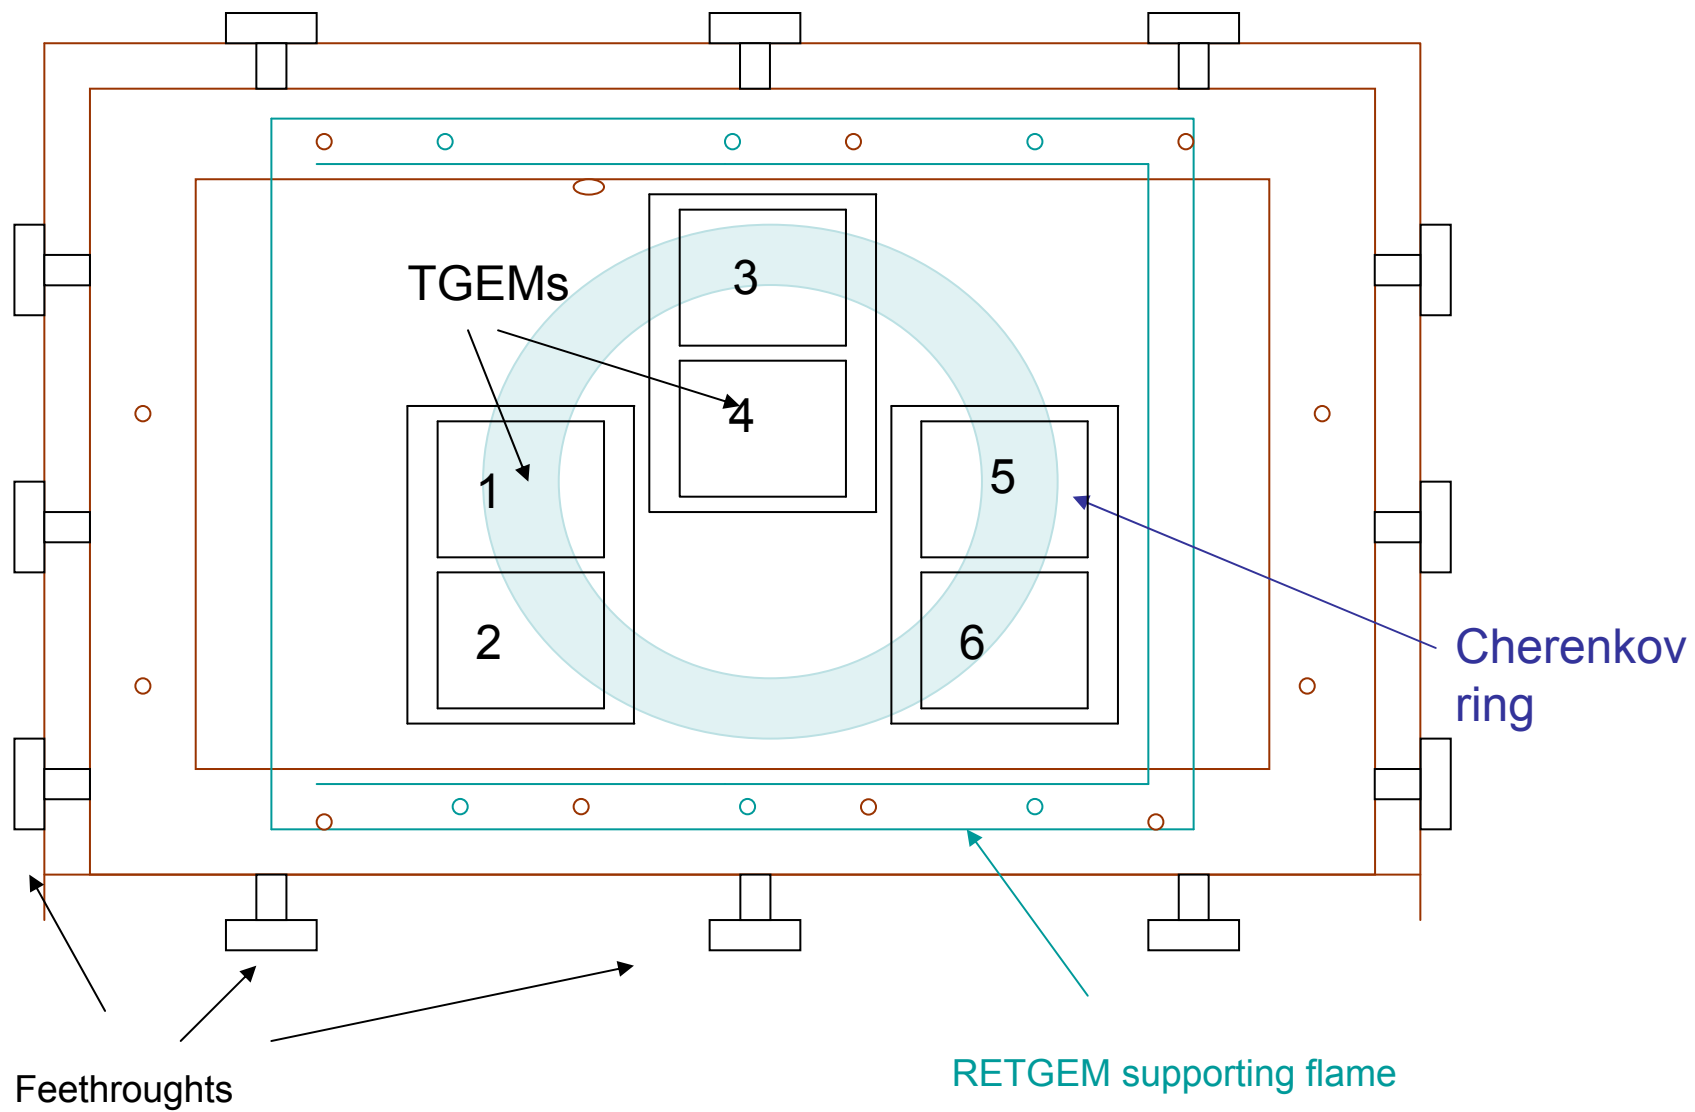

# Design of the CsI-TGEM based RICH prototype

# The top view of the RICH prototype (from the electronics side)

# View from the back plane

# Csl side

# Drift meshes (three independent grids)

# Voltage dividers

There was a possibility to independently observe analog signals from any of electrodes of any TGEM and if necessary individually optimize voltages on any TGEM

Six triple TGEMs were assembled using a glow box inside the RICH prototypes gas chamber.

# Front view

The RICH prototype has windows in front of each triple TGEM allowing to irradiate the detectors either with the radioactive sources such as  $^{55}\text{Fe}$  or  $^{90}\text{Sr}$  or with the UV light from a Hg lamp

# Laboratory tests

Before the installation to the RICH detector, each TGEM was individually tested in a separate small gas chamber.

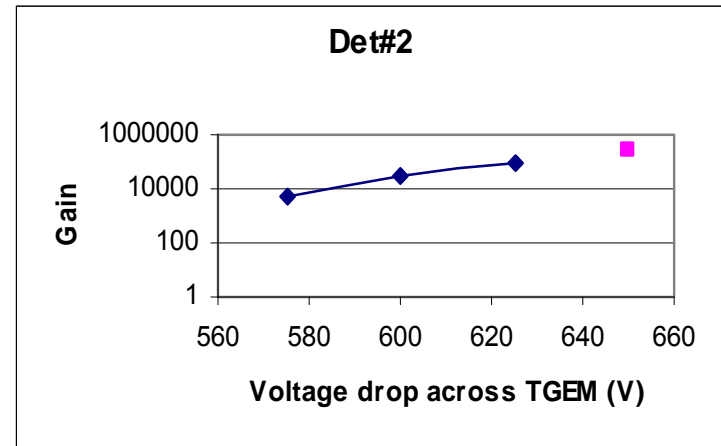

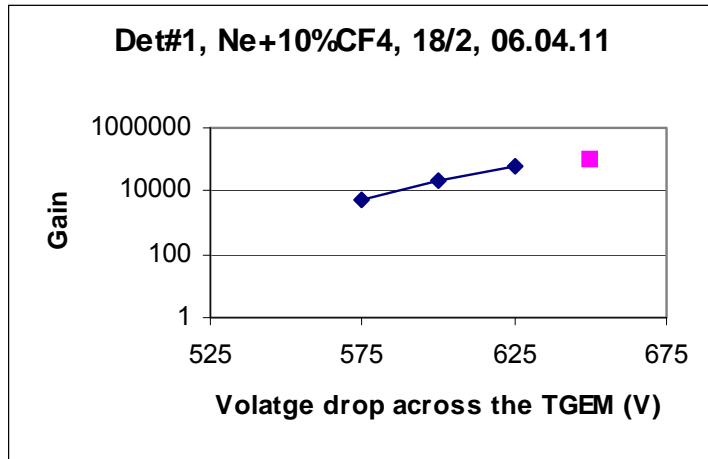

In these tests we mainly identified the maximum achievable gains when the detectors were irradiated with the  $^{55}\text{Fe}$  source and with the UV light.

# Summary of single TGEMs performance

# Typical results of gas gain measurements for triple Csl-TGEMs

Gains in the range  $3 \cdot 10^5$ - $10^6$  were achieved

Measurements were performed when the detectors were simultaneously irradiated with  $^{55}\text{Fe}$  and UV light and  $^{90}\text{Sr}$  source

# Stability?

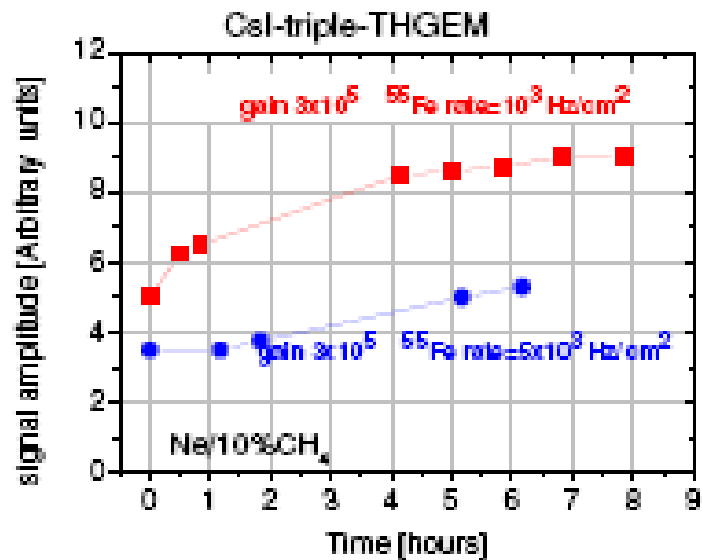

Figure 15. Short-term stability of a triple-THGEM (rim 0.1 mm) with CsI photocathode measured in Ne+10%CH<sub>4</sub> at a) at overall gain of  $3 \times 10^5$  and counting rate of  $\sim 1 \text{ kHz/cm}^2$  and b) an overall gain of  $3 \times 10^5$  and counting rate of  $\sim 5 \text{ kHz/cm}^2$ .

We have solved the stability problems by constantly keeping some voltages over TGEMs

PS. The variations above correlated to the atmospheric pressure changes

## QE measurements before CsI-TGEM installation into the RICH prototype

The QE value is about 16% less than in the case of the best CsI-MWPC

# Beam test

Our proximity focusing TGEM-based RICH prototype installed at CERN T10 beam test facility (mostly  $\sim 6$  GeV/c pions)

Electronics side

# Some results

# Single events display

Run: 3689 Event: 10

Run: 3689 Event: 43

Run: 3689 Event: 197

Run: 3689 Event: 242

Ne+10%CH<sub>4</sub>  
(overlapping events, radiator thickness 10mm)

November 2010 beam test. Noise was removed offline

# Ne+10%CF<sub>4</sub> (overlapping events, rad. thickness 15 mm)

Summed event display, Run: 3689 Event: 27811

May 2011 beam test. Raw data, no noise removal

## Some examples of data

**Main conclusion : ~1p.e. per TGEM**

## Four triple TGEMs together

After corrections on geometry and nonuniformity of the detector response the estimated mean total number of photoelectrons per event is about **10.2**

How much p.e one can expect in “ideal conditions”: full surface (without holes) and CH<sub>4</sub> gas:  
 Corrections: 0.9 (extraction)x0.75=0.68  
 10p.e/0.68~ **15pe**

## What was achieved in the past with the CsI-MWPC (radiator 15mm)?

Fig. 3. Single Cherenkov ring event with the three zones used for cluster finding. A pad unit is  $8 \times 8 \text{ mm}^2$ .

Radiator 15mm

# QE scan after the beam test

Conclusion from the scan: the QE of the CsI layer on the top of TGEMs is practically the same as before our tests - about 16% less than in the case of good MWPC - so corrected on this the total number of expected p.e. will be around **16-17**-close enough to the MWPC data

# Developing the simulation program

## Some details, how simulation was done.

Input parameters: geometry, n-index, gas (ionization, diffusion), E-field, Average Gas Amplification, FEE parameters,...

- Primary ionization: track, Fe55 (position in a space of each e-), single photo-electron from CsI on a top of a first foil (GEANT-3 for UV production, transport and CsI QE)
- Transport of each e- to nearest hole in first foil (probability and position in a hole)
- Gas amplification; Polya distribution and “some special parameters”.
- Transfer of each e- after gas amplification step to next foil (hole selection)
- Repeat GA and Transport steps for second and third foil.
- Collect electrons on pad (strip) structure
- Add FEE noise and response for each (“active”) pad
- Threshold to select “active” pads.
- Cluster finding and reconstruction.
- **NO Background (for the moment)**

# Some preliminary results of the simulation

Red-experimental data  
Blue-calculations

Number of reconstructed clusters per trigger (assumption  $QE=0.66QE$  in  $CH_4$ ), so  $\sim 35\%$  accuracy

# Conclusions:

- **For the first time** Cherenkov rings were detected with CsI-TGEMs
- The mean number of detected photoelectrons is the same as expected from estimations
- Thus, preliminary It looks that TGEM is an attractive option for the ALICE VHMPID: it can operate in inflammable gases with a relatively high QE, it has a fast signals and cetera
- Of course, the final choice of the photodetector for VHMPID will be based on many considerations, for example MWPC approach has its own strong advantage: it is a well proven technology

# Aknowledgments:

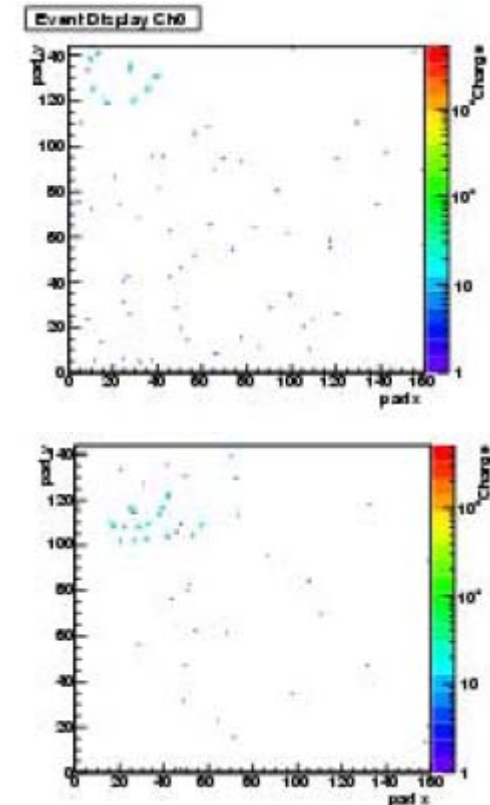

Author would like to thank J. Van Beelen, M. Van Stenis and M. Webber for their help throughout this work

Spare

# The main advantages of MWPC- it is a proven technology

## The current ALICE/HMPID Detector

- 7 modules:
- total area 11 m<sup>2</sup>

See [A. Di Mauro](#) talk at his Conference

First Cherenkov rings candidates at 7TeV  
proton-proton collisions at LHC

# Rate dependance

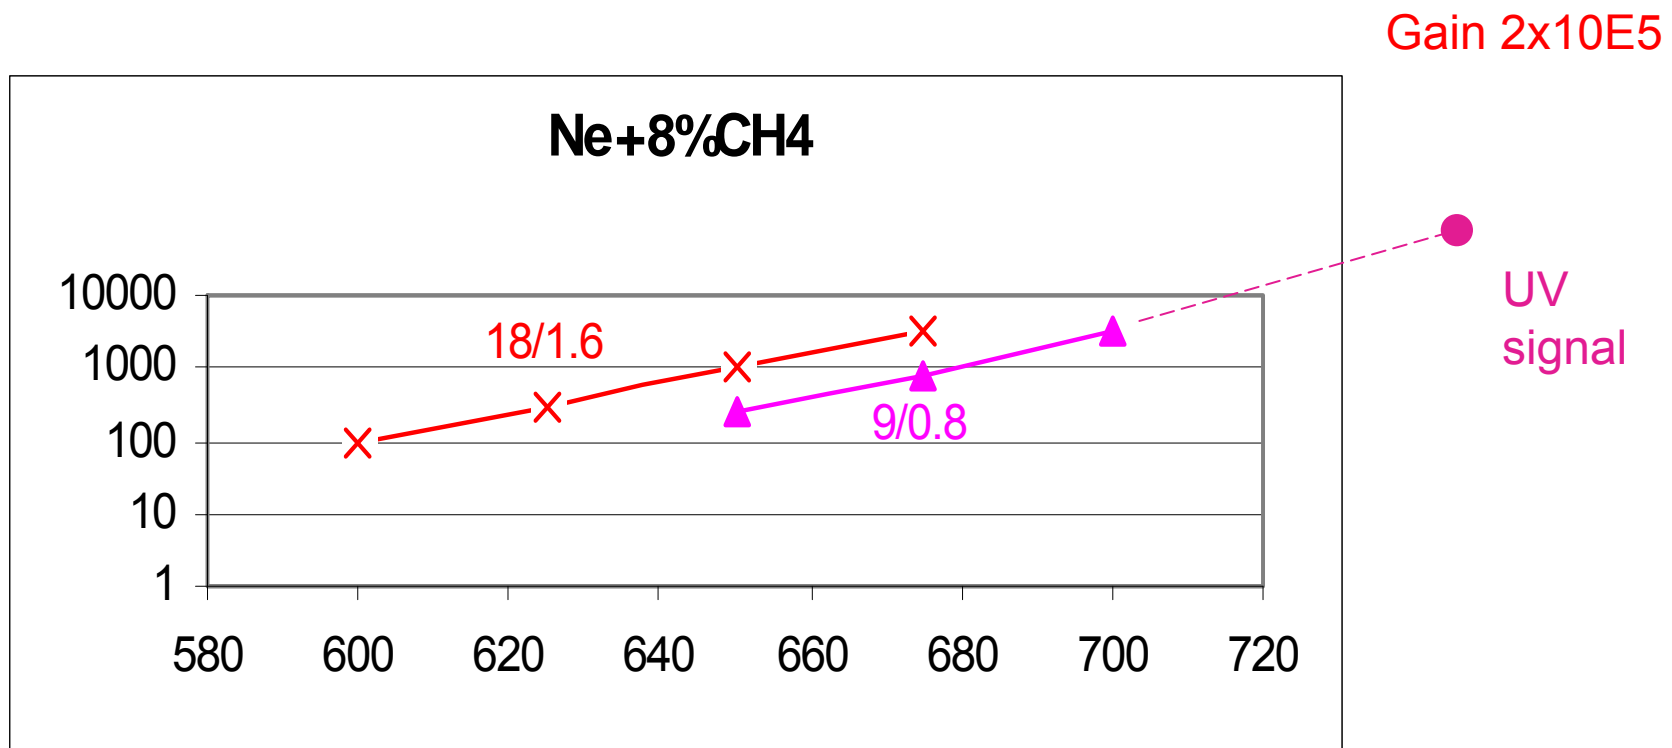

Triple TGEM is inside this general limit!.. So at the beam test we should not expect an unlimited gain

# Measurements with $^{55}\text{Fe}$

The gas flow at the beam test was 27/3

# Measurements with $^{55}\text{Fe}$

No flow dependence in the given region
